# Front-end assignments

Create a single page application using HTML, CSS, JS and jQuery (may use BootStrap later once you have good grasp on CSS topics) where there will be:
  - A table showing the tourist places of Bangladesh (with columns for Name, Address, Rating, Picture and Action Buttons)
  - Each row will contain information about a tourist place along with buttons to update and delete that row
  - A form with labels and input fields which will allow the user to a) add a new tourist place, b) update an existing tourist place
  - Implement sorting on the rating column (ASC, DESC, None)
  - Implement search-as-you-type searching (partial match) by tourist places' name(s)
  - The app will be front-end only, which means, the data will not be persisted, refreshing the page will result in the existing data (if any) to be cleared
